he receives the order to fire. As the pellets break the wire, the chronograph, which is an electric time-recording instrument, is set in motion. This device is halted automatically when the pellets strike the target, which is also connected electrically with the chronograph. Translating the elapsed time into feet-per-second gives the velocity of the shot.

The "time-up-the-barrel" test, to determine the speed and uniformity of the primer, is a variation of the velocity test, but is confined to the time it takes the shot to pass through the barrel. When the gun is fired, the hammer raises a ball bearing in its socket, setting a second chronograph into operation. When the pellets strike a second copper wire stretched in front of the muzzle of the barrel, the

chronograph is automatically halted, and the elapsed "time-up-the-barrel" is recorded in ten-thousandths of a second. Average "time-up-the-barrel" for a 12-gauge skeet shell is .0030 seconds.

The amount of gas or breech pressure generated by the burning of smokeless powder must be carefully controlled in shotshells. The pressure is determined by directing the expanding gases to shorten or compress a clear lead cylinder.

A hole, exactly $1/25$ of a square inch, is drilled through the gun barrel one inch from the breech. Into this hole is placed a piston upon which rests the lead cylinder which "records" the pressure. When the shell is fired, the upward movement of the piston compresses the cylinder. The amount of com-
